As the nature of these eastern borders is set in stone, many human of lymphatic origin are 30 to 70 years, whereas for cancers of the gastrointestinal tract, more cancers occur at an earlier age.

Non-Hodgkin lymphoma (NHL) is a type of lymphoma that can affect the lymph nodes and other lymph tissues throughout the body. NHL is most commonly found in lymph nodes and other lymph tissues, although it can also occur in the skin.

**Therapy**

Therapies for NHL can include chemotherapy, radiation therapy, immunotherapy, and stem cell transplantation. The choice of therapy depends on the type and stage of NHL, as well as other factors such as the patient's age and overall health.

**Prognosis**

The outlook for NHL varies depending on the type and stage of the disease. Some types of NHL have a good prognosis, while others have a worse prognosis.

**Research**

Research is ongoing to develop new treatments for NHL, including new drugs and therapy combinations.

**Conclusion**

Non-Hodgkin lymphoma is a complex disease with a variety of causes and treatments. Ongoing research is helping to improve treatment outcomes for patients with NHL.
